

# Selected work samples

Product design / Service design / Systems thinking

A concise selection of internal work shared for recruitment review.

# How I work

I make complex products easier to understand, use and deliver by connecting research, interface decisions and team practices.

## Design systems

Audit inconsistency, document decisions and create reusable patterns that teams can apply with confidence.

## Product workflows

Translate observed behaviour into feasible interaction patterns, then validate them with users.

## Service design

Map people, processes and systems so teams can reason about a shared end-to-end service.

## Selected evidence

01

### PALMS design system

Governance, reusable templates and documented foundations.

02

### Kaizen action workflow

A status-based board derived from user behaviour and tested with four participants.

03

### PLM service blueprint

Research synthesis across 16 interviews and eight business groups.

#### SCOPE NOTE

The following images are selected excerpts from internal work. Names, detailed research notes, internal links and operational data have been omitted. Outcomes distinguish my contribution from wider project results.

# From inconsistency to shared foundations

I helped turn scattered product decisions into a usable system for designers, analysts, engineers and testers.

## MY CONTRIBUTION

- Audited the live product, existing library and working files to identify component and implementation mismatches.
- Structured colour, typography, icon and component guidance around usage, behaviour, accessibility and responsive application.
- Established contribution rules and added formal design review to the front-end delivery process.

## Outcome

The updated component library reached 100% adoption within the design team. No further design-to-build misalignment was reported during the observed period after formal design review was introduced.

# Guidance that supports real delivery

The system paired reusable page patterns with practical instructions for choosing, applying and reviewing components.

## What this evidence shows

- Component documentation covers when to use the pattern, states, anatomy, formatting and accessibility.
- Boilerplate pages give teams approved starting points for common product structures.
- The icon guidance standardises library use; it does not claim authorship of the underlying MUI icon set.

### Design principle

A design system becomes valuable when decisions are discoverable and the delivery process checks that the built experience still reflects them.

# Turning an observed behaviour into a feasible MVP

Users were already arranging spreadsheet columns like a Kanban board when presenting and tracking actions.

## Evidence

Interview observation revealed an existing status-based mental model.

## Decision

Organise actions by status and due date; defer drag and drop to control delivery effort.

## Validation

Four usability sessions; all participants understood the board without prompting.

## My role

I contributed to research planning and synthesis, identified the recurring behaviour, checked technical feasibility with engineering leads and proposed the board direction. The approved pattern was released without drag and drop in its initial version.

# Making a fragmented service visible

Checklist work crossed paper forms, digital PDFs, field activity and enterprise systems. A shared view was needed before the team could prioritise a direction.

## Research and synthesis

- 16 interviews across eight business groups, covering common needs and specialised workflows.
- A layered blueprint linked the generic process, customer journeys, roles, product touchpoints, supporting systems and handoffs.
- Pain points were placed at the exact stage where they occurred so visible user problems could be connected to operational or technical causes.

## My contribution

I participated in planning and every interview, organised the findings, independently created the service blueprint and validated system relationships with the Solution Architect.

# One model for people, product and systems

The blueprint preserved differences between customer groups while making shared stages and dependencies easy to compare.

## Why this structure

Separate journey maps would preserve detail but make comparison difficult. A single generic process would erase role-specific requirements.

## How it helped

Design, business and technology could identify common and specialised needs, trace dependencies and agree on an initial direction.

## Responsible outcome statement

The work later progressed into design and development. I did not participate in the later stakeholder review, so I describe that progression as a project outcome rather than a result directly delivered by me.

## CLOSING NOTE

# Thank you for reviewing

I would be happy to talk through the decisions, constraints and collaboration behind these examples in an interview.

## WHAT I BRING

- Structured thinking across products, services and delivery systems
- Clear documentation that helps cross-functional teams act
- Evidence-led decisions balanced with engineering feasibility
- Honest ownership of contribution, outcomes and limitations
